

1. When you have finished 1-8 on page 12 you are ready to calculate the acceleration of the freely-falling object in SI units, as requested in #9:
  - a. The definition of "acceleration" on RSI says we must divide the object's change in \_\_\_\_\_ by the corresponding change in \_\_\_\_\_.
  - b. To determine the *units* of that quotient you must \_\_\_\_\_ the SI speed unit mentioned in #8b by the SI \_\_\_\_\_ unit mentioned in #6b, using the usual rules of algebra. In other words, you must divide "\_\_\_\_\_s per \_\_\_\_\_" by "\_\_\_\_\_s" exactly as we did in #9 on page 9.
  - c. Remember that "per" means "over" or "divided by", so one of the units has the form of a *fraction*. The rule for dividing fractions is reviewed in #9 on page 9. It says we must "invert the \_\_\_\_\_ and then \_\_\_\_\_."
  - d. Simplifying the result, we find that the SI unit of acceleration must be "\_\_\_\_\_ per \_\_\_\_\_".
  - e. To find the GLV of the acceleration (*in standard units*) you must divide the \_\_\_\_\_LV of the change in \_\_\_\_\_ by the \_\_\_\_\_LV of the falling \_\_\_\_\_ interval.
  - f. Those two numbers can be copied from #\_\_\_\_ and #\_\_\_\_ on page 12:  
**GLV of** \_\_\_\_\_ = ( \_\_\_\_\_ ) ÷ ( \_\_\_\_\_ ) = \_\_\_\_\_
  - g. To find the SLV of the acceleration you divide the \_\_\_\_\_LV of the \_\_\_\_\_ by the \_\_\_\_\_LV of the \_\_\_\_\_. (See #7 on page 4.) Those numbers are *also* recorded in #\_\_\_\_ and \_\_\_\_\_ on page 12:  
**SLV of** \_\_\_\_\_ = ( \_\_\_\_\_ ) ÷ ( \_\_\_\_\_ ) = \_\_\_\_\_
2. The last step is to change from centimeters to meters by moving the decimal point \_\_\_\_\_ jumps to the \_\_\_\_\_. (For example, 150 cm. = \_\_\_\_\_ meter.) Now we can write a conclusion in SI units:
  - a. "The acceleration of a freely falling object is between \_\_\_\_\_ and \_\_\_\_\_ per \_\_\_\_\_." Using #16 on RS I, we get "acceleration = \_\_\_\_\_ ± \_\_\_\_\_."
  - b. "The acceleration of a freely falling object is \_\_\_\_\_ ± \_\_\_\_\_%"
  - c. We measured the distances between dots with an uncertainty of ± \_\_\_\_\_ cm. The uncertainty of the falling time interval in 3b was ± \_\_\_\_\_ ticks. The uncertainty of the frequency in #6 was ± \_\_\_\_\_%. Most of the uncertainty in our final result must be blamed on our lack of precision in measuring the \_\_\_\_\_.
3. Page 66 of the PSSC textbook (page 76 in the L-2 book) says that the acceleration of a freely falling object near the earth's surface is approximately \_\_\_\_\_ - Does #2 (above) agree with that statement? \_\_\_\_\_ The negative sign given in the book is there to remind us that this acceleration is in the \_\_\_\_\_ward direction.
4. That acceleration is being recorded for future reference in # \_\_\_\_\_ on the Chapter \_\_\_\_\_ review sheet, which is called "RS I".
